Mathematics of Networks 2014 - Imperial College London, Sept. 10, 2014
Outline

- General formalism for multiplex networks
- Measures to characterise the multiplexity of a system
  1. Basic node and link properties
  2. Local properties (clustering)
  3. Global properties (transitivity, reachability, centrality)
- Validation of all measures on a genuine multi-layer dataset of Indonesian terrorists
A multiplex is a system whose basic units are connected through a variety of different relationships. Links of different kind are embedded in different layers.

- **Node index** \( i = 1, \ldots, N \)
- **Layer index** \( \alpha = 1, \ldots, M \)
General formalism for multiplex networks

A multiplex is a system whose basic units are connected through a variety of different relationships. Links of different kind are embedded in different layers.

- **Node index** \( i = 1, \ldots, N \)
- **Layer index** \( \alpha = 1, \ldots, M \)

For each layer \( \alpha \):

- **adjacency matrix** \( A^{[\alpha]} = \{a_{ij}^{[\alpha]}\} \)
- **node degree** \( k_i^{[\alpha]} = \sum_j a_{ij}^{[\alpha]} \)
- \( \sum_i k_i^{[\alpha]} = 2K^{[\alpha]} \) \( K^{[\alpha]} \) is the size of layer \( \alpha \)
General formalism for multiplex networks

A multiplex is a system whose basic units are connected through a variety of different relationships. Links of different kind are embedded in different layers.

- Node index \( i = 1, \ldots, N \)
- Layer index \( \alpha = 1, \ldots, M \)

For each layer \( \alpha \):

- adjacency matrix \( A^{[\alpha]} = \{a_{ij}^{[\alpha]}) \}
- node degree \( k_i^{[\alpha]} = \sum_j a_{ij}^{[\alpha]} \)
- \( \sum_i k_i^{[\alpha]} = 2K^{[\alpha]} \) \( K^{[\alpha]} \) is the size of layer \( \alpha \)

For the multiplex:
- vector of adjacency matrices \( A = \{A^{[1]}, \ldots, A^{[M]} \} \).
- vector of degrees \( k_i = (k_i^{[1]}, \ldots, k_i^{[M]}). \)

Vectorial variables are necessary to store all the richness of multiplexes.
General formalism: aggregated matrices

Aggregated topological network:

- adjacency matrix $\mathcal{A} = \{a_{ij}\}$:
  \[
  a_{ij} = \begin{cases} 
  1 & \text{if } \exists \alpha : a_{ij}^{[\alpha]} = 1 \\
  0 & \text{otherwise}
  \end{cases}
  \]  
  (1)

- node degree $k_i = \sum_j a_{ij}$
- $\sum_i k_i = 2K$
General formalism: aggregated matrices

Aggregated topological network:
- adjacency matrix $A = \{a_{ij}\}$:
  \[ a_{ij} = \begin{cases} 
  1 & \text{if } \exists \alpha : a_{ij}^{[\alpha]} = 1 \\
  0 & \text{otherwise}
  \end{cases} \quad (1) \]
- node degree $k_i = \sum_j a_{ij}$
- $\sum_i k_i = 2K$

Aggregated overlapping network:
- adjacency matrix $O = \{o_{ij}\}$:
  \[ o_{ij} = \sum_\alpha a_{ij}^{[\alpha]} \text{ edge overlap} \quad (2) \]
- node degree $o_i = \sum_j o_{ij} = \sum_\alpha k_i^{[\alpha]}$, $o_i \geq k_i$
- $\sum_i o_i = 2O$
General formalism: aggregated matrices

Aggregated topological network:
- adjacency matrix $A = \{a_{ij}\}$:
  
  $$a_{ij} = \begin{cases} 
  1 & \text{if } \exists \alpha : a_{ij}^{[\alpha]} = 1 \\
  0 & \text{otherwise} 
  \end{cases}$$  
  
  (1)

- node degree $k_i = \sum_j a_{ij}$
- $\sum_i k_i = 2K$

Aggregated overlapping network:
- adjacency matrix $O = \{o_{ij}\}$:
  
  $$o_{ij} = \sum_{\alpha} a_{ij}^{[\alpha]} \text{ edge overlap}$$  
  
  (2)

- node degree $o_i = \sum_j o_{ij} = \sum_{\alpha} k_i^{[\alpha]}$, $o_i \geq k_i$
- $\sum_i o_i = 2O$

Scalar variables describing system’s multiplexity cannot disregard the layer index $[\alpha]$.
Generalisation to the case of weighted layers: $a_{ij}^{[\alpha]} \rightarrow w_{ij}^{[\alpha]}$, $k_i^{[\alpha]} \rightarrow s_i^{[\alpha]}$, $o_{ij} \rightarrow o_{ij}^w$
The multi-layer network of Indonesian terrorists

- 78 nodes

- 911 edges representing 4 social relationships:
  1. Trust (weighted edges)
  2. Operations (weighted edges)
  3. Communications
  4. Business (only few information)

Basic node properties

A layer-by-layer exploration of node properties: the case of the degree distribution.

Different layers show different patterns.
Basic node properties: cartography of a multiplex

### Participation coefficient:

\[ P_i = 1 - \sum_{\alpha=1}^{M} \left( \frac{k_i^{[\alpha]}}{o_{i}} \right)^2 \]

1. **Focused nodes**  \( 0 \leq P_i \leq 0.3 \)
2. **Mixed-pattern nodes**  \( 0.3 < P_i \leq 0.6 \)
3. **Truly multiplex nodes**  \( P_i > 0.6 \)

### Z-score of the overlapping degree:

\[ z_i(o) = \frac{o_i - \langle o \rangle}{\sigma_o} \]

1. **Simple nodes**  \(-2 \leq z_i(o) \leq 2\)
2. **Hubs**  \( z_i(o) > 2 \)
Basic node properties: cartography of a multiplex

(a) Graph showing the rank against the property $P_i$ for nodes.

(b) Scatter plot of $z_i(o)$ vs. $P_i$ for hubs and nodes.

(c) Graph illustrating the focused, mixed, and multiplex categories.
Edge overlap and social reinforcement

Probability conditional overlap:

$$F(a^{[\alpha']}_{ij} | a^{[\alpha]}_{ij}) = \frac{\sum_{ij} a^{[\alpha']}_{ij} a^{[\alpha]}_{ij}}{\sum_{ij} a^{[\alpha]}_{ij}}$$

(3)
Edge overlap and social reinforcement

\[ F(a^{[\alpha']}_{ij} | a^{[\alpha]}_{ij}) \rightarrow F^{w}(a^{[\alpha']}_{ij} | w^{[\alpha]}_{ij}) \]

The existence of strong connections in the Trust layer, which represents the strongest relationships between two people, actually fosters the creation of links in other layers.
Triads and triangles

1-triad

2-triad

1-triangle

2-triangle

3-triangle
Clustering

\[ C_{i,1} = \frac{\sum_\alpha \sum_{\alpha' \neq \alpha} \sum_{j \neq i, m \neq i} (a_{ij}^{[\alpha]} a_{jm}^{[\alpha']} a_{mi}^{[\alpha]})}{\sum_\alpha \sum_{j \neq i, m \neq i} (a_{ij}^{[\alpha]} a_{mi}^{[\alpha]})} \] (4)
Clustering

\[ C_{i,1} = \frac{\sum_\alpha \sum_{\alpha' \neq \alpha} \sum_{j \neq i, m \neq i} a_{ij}^{[\alpha]} a_{jm}^{[\alpha']} a_{mi}^{[\alpha]}}{\sum_\alpha \sum_{j \neq i, m \neq i} a_{ij}^{[\alpha]} a_{mi}^{[\alpha]}} \]  

\[ C_{i,2} = \frac{\sum_\alpha \sum_{\alpha' \neq \alpha} \sum_{\alpha'' \neq \alpha, \alpha'} \sum_{j \neq i, m \neq i} a_{ij}^{[\alpha]} a_{jm}^{[\alpha'']} a_{mi}^{[\alpha']} \sum_\alpha \sum_{j \neq i, m \neq i} a_{ij}^{[\alpha]} a_{mi}^{[\alpha']} }{\sum_\alpha \sum_{\alpha' \neq \alpha} \sum_{j \neq i, m \neq i} a_{ij}^{[\alpha']} a_{mi}^{[\alpha']} } \]
Transitivity

\[ T_1 = \frac{\text{# of}}{\text{# of}} \text{ in the multiplex} \]

\[ T_2 = \frac{\text{# of}}{\text{# of}} \text{ in the multiplex} \]
$C_{i,1}$ and $C_{i,2}$ show different patterns of multi-clustering and are not correlated with $o_i$. 
Transitivity and clustering

We call configuration model (CM) the set of multiplexes obtained from the original system by randomising edges and keeping fixed the sequence of degree vectors \( k_1, k_2, \ldots, k_N \), i.e. keeping fixed the degree sequence at each layer \( \alpha \).

<table>
<thead>
<tr>
<th>Variable</th>
<th>Real data</th>
<th>Randomised data</th>
</tr>
</thead>
<tbody>
<tr>
<td>( C_1 )</td>
<td>0.26</td>
<td>0.17</td>
</tr>
<tr>
<td>( C_2 )</td>
<td>0.26</td>
<td>0.18</td>
</tr>
<tr>
<td>( T_1 )</td>
<td>0.21</td>
<td>0.15</td>
</tr>
<tr>
<td>( T_2 )</td>
<td>0.21</td>
<td>0.16</td>
</tr>
</tbody>
</table>

Measures of multi-clustering for real data are systematically higher than the ones obtained for randomised data, where edge correlations are washed out by randomisation.
Navigability: shortest paths and interdependence

The interdependence $\lambda_i$ of node $i$ is defined as:

$$\lambda_i = \sum_{j \neq i} \frac{\psi_{ij}}{\sigma_{ij}}$$

(6)

where $\sigma_{ij}$ is the total number of shortest paths between $i$ and $j$ and $\psi_{ij}$ is the number of interdependent shortest paths between node $i$ and node $j$. 
Reachability: shortest paths and interdependence
Centrality

For a duplex we can construct the following adjacency matrix:

$$\mathcal{M}(b) = bA^{[1]} + (1 - b)A^{[2]}, \quad \mathcal{M}(b = 0.5) = \mathcal{O}$$

(7)

The symmetry/asymmetry of the curves tell us about the interplay between the layers in determining the centrality of the multi-layer system. Both layers T and O dominate C in determining the centrality of the multiplex.
Summary

- We suggested a comprehensive formalism to deal with systems composed of several layers

- We also proposed a number of metrics to characterize multiplex systems with respect to:
  1. Node degree
  2. Node participation to different layers
  3. Edge overlap
  4. Clustering
  5. Transitivity
  6. Reachability
  7. Eigenvector centrality
  8. You can find more in the paper
