# What do we mean by network geometry??

- Nodes have coordinates in some space
- Whether an edge exists is a function of the node's coordinates

# 2D Random Geometric Graph

# Hyperbolic geometry

# Hyperbolic network geometry

# Hyperbolic network geometry

# Riemannian and Lorentzian Geometry

- Euclidean space, hyperbolic space, the surface of a sphere etc. are all Riemannian geometries
- The *eigenvalues* of the metric are all positive
- Euclidean space:  $ds^2 = dx^2 + dy^2 + dz^2$   
Sphere surface:  $ds^2 = d\theta^2 + \sin(\theta)d\phi^2$

# Riemannian and Lorentzian Geometry

- In this talk - Lorentzian Geometry
- One eigenvalue of the metric is negative
- The most well known example is Minkowski space - the geometry of special relativity where  $ds^2 = -dt^2 + dx^2 + dy^2 + dz^2$
- Distances can be positive, negative or 0.

# Simplest example: Minkowski space

# Causal Sets

- A link back to physics - causal sets
- Approach to quantum gravity where spacetime is a set of discrete points that approximate the continuous spacetime we perceive
- Relations in the causal set correspond to timelike separation

# 1+1 dimensional causal set

# Causal Sets

- Causal sets  $\rightarrow$  Directed Acyclic Graph.
- Interesting properties - Lorentz invariance.
- Geodesic is the *longest chain* and not the shortest.
- Unbounded number of nearest neighbours.

# Minkowski space

# Lorentzian Random Geometric Graphs

# Lorentzian Random Geometric Graphs - phase transition

## Lorentzian Random Geometric Graphs - scaling

# Real networks

- Lots of real networks have some kind of approximate Euclidean/hyperbolic geometry
- Do any have approximate Lorentzian geometry?
- Clues - nodes exist at a certain point in time, and edges represent causal connections between them
- Network forms a Directed Acyclic Graph (DAG)

# Let's speculate: Citation Networks?

- Documents appear at a particular time.
- They (usually) can only cite something written in the past, and so form a DAG.
- Academic papers - spatial dimensions could correspond to different academic fields?
- Citations in the same field have a shorter timespan than citations to different fields - suggestive of this kind of geometry?

# Citation Networks

- Assume there is some Lorentzian geometry and see what we can measure
- I said before that the *longest chain* is a good approximation to the geodesic and not the shortest
- Traditional centrality measures use the shortest path as a measure of distance - what if we use the longest?

## Example - 1+1 random Minkowski space network

## Example - 1+1 random Minkowski space network

## Example - 1+1 random Minkowski space network

## Example - 1+1 random Minkowski space network

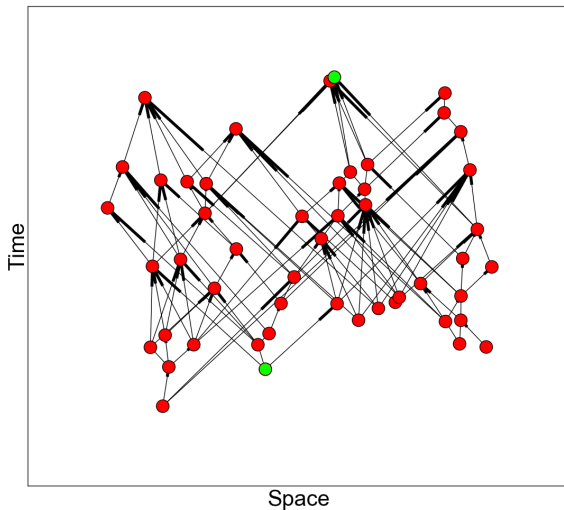

# Example - 1+1 random Minkowski space network

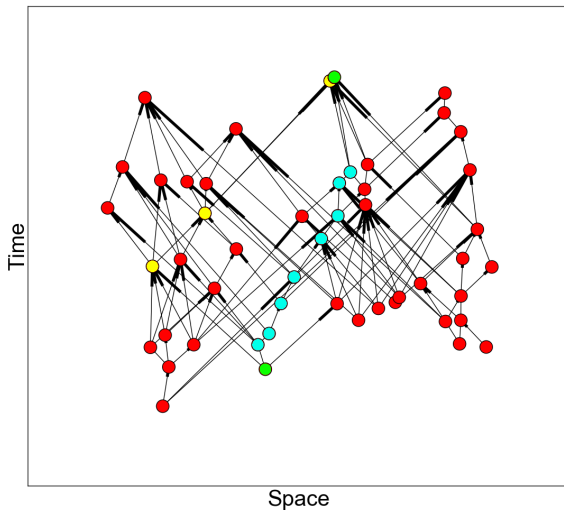

## Example - 1+1 random Minkowski space network

## Example - 1+1 random Minkowski space network

## Example - 1+1 random Minkowski space network

# Test on small citation network

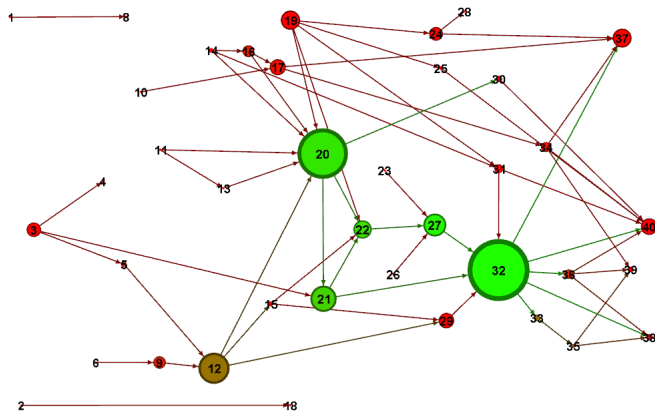

Fig. 1. DNA theory network.

# Test on small citation network

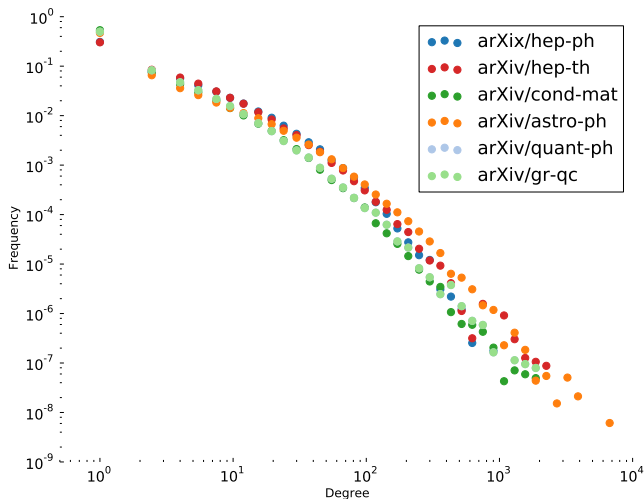

# Test on small citation network

# Characterising the Lorentzian Space

- Can we characterise the space the network is embedded in?
- Simplest example - Minkowski space - only 1 parameter - dimension.
- By measuring how the population of the network scales with a length scale (longest path) we can estimate a dimension.
- Does this tell us anything interesting about real networks?

# Degree distributions similar

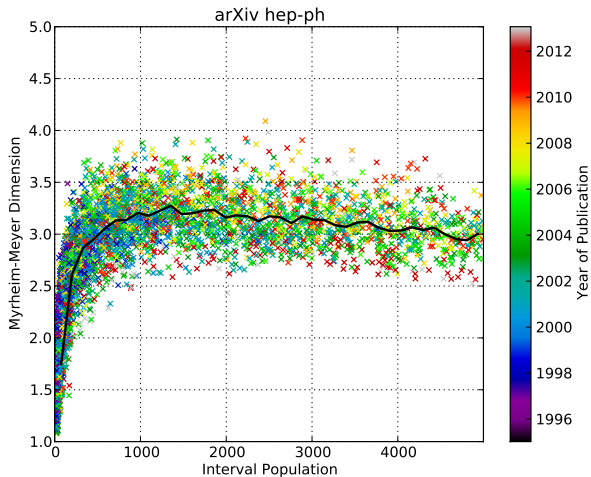

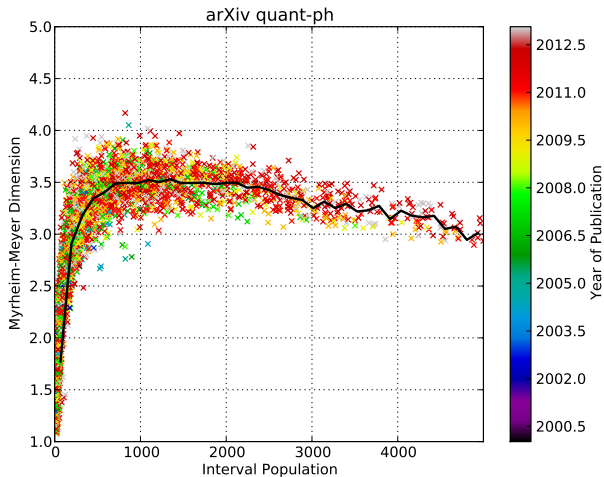

# Dimension estimates different

# Dimension estimates different

# Dimension estimates different

# Dimension estimates different

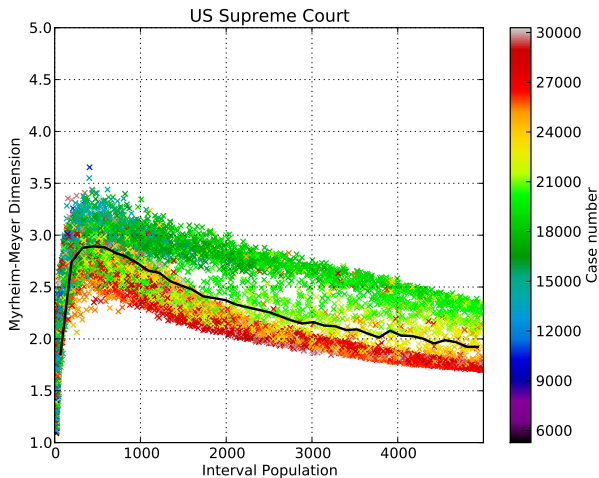

# Dimension estimates different

# Discussion

- Networks with very similar degree distributions and clustering have very different ‘dimensions’.
- This method provides a new way of quantifying a characteristic of the structure of citation networks.
- Measuring properties of the embedding space (dimension, curvature etc.) is needed before we can try to embed the network (i.e. ‘find’ the coordinates of each node)

# US Supreme Court Citation Network

# Discussion

- Citation behaviour changes over time.
- Citation networks from different fields have very different structure - can we measure different kinds of citation behaviour?
- Possible interpretation - high dimension  $\rightarrow$  more diverse citation behaviour.

# Future direction?

- How can we better determine when it's useful to say a network has some geometric properties?
- What other ways of characterising those spaces are there? And how do we interpret them?
- What can we learn about individual nodes in a network by finding a way to embed them in a space?
