Autonomous Mobile Programs (AMPs)

AMPs are mobile agents

- aware of their resource needs
- sensitive to the execution environment
- periodically seek a better location

 $T_{h} > T_{n} + T_{comm}$ (1) Time on the > Min time on + Time to transfer current location fastest network location

- Been investigated using
 - Mobile languages (e.g. Java Voyager [DMT10])
 - Simulation [CKPT09]

Greedy Effect	s			

- are redundant movements:
 - locally optimal choice, but
 - globally non-optimal choice
- occur when AMPs rebalance after a termination or new AMPs start
- are observed in other distributed systems

Natalia Chechina, Peter King, Phil Trinder

Dependable System Group, Heriot-Watt University

Location Thrashing

Due to lack of information about other AMPs intending to move to the same location

Negotiating AMPs

- Reduce greedy effects by sharing information
- Methods of AMP negotiation: Malicious/Honest: queuing, competitive, probabilistic, relationship, etc.
- cNAMPs are negotiating AMPs with a competitive scheme:
 - announce their intentions to move
 - compete with each other for faster locations
- cNAMPs eliminate location thrashing

Natalia Chechina, Peter King, Phil Trinder

Dependable System Group, Heriot-Watt University

Networks & Locations

Types of Networks

- Homogeneous network: all locations have the same CPU speed, except the initiating location
- ▶ Heterogeneous network: locations have different CPU speeds
 - Subnetwork is a set of locations with identical CPU speeds

Types of Locations

- Root location where all cNAMPs start
- Heavy location has optimal number of cNAMPs
- Light location has one cNAMP less than heavy location

Natalia Chechina, Peter King, Phil Trinder

Definitions				

Balanced States

In a balanced state no cNAMP can gain a greater relative speed by moving

- In optimal balance locations with the same CPU speed have equal number of cNAMPs
- In near-optimal balance
 - Iocations of one subnetwork have different number of cNAMP
 - the discrepancy is at most one cNAMP

イロト イポト イヨト イヨト

Conclusion & Future Work

We have

- Identified two types of the greedy effects
- Introduced negotiating AMPs (cNAMPs) to eliminate location thrashing
- Used case analysis to prove absolute bounds on greedy effect (3)-(7)
- Used statistical analysis to prove median probability of redundant movements
- Proved properties about collections of cNAMPs, e.g. the maximum number of redundant movements that may occur

Future Work

► Investigation of cNAMP behaviour on wide area networks.

Termination at a Non-root Location

After a cNAMP termination from optimally balanced homogeneous network, the system has $\left[\left[\frac{f(2k+1)-1}{2(f+1)}\right]\right]$ cNAMPs on the root location, $\left[\left[\frac{2k-3f-1}{2(f+1)}\right]\right]$ cNAMPs on a non-root location, and $\left[\left[\frac{2k-f+1}{2(f+1)}\right]\right]$ cNAMPs on the remaining non-root locations.

Now we analyse possible movements which may occur from the root location to the light location. First, we calculate cNAMP execution time on the root location before a cNAMP movement:

$$T_{h} = \frac{W_{r}}{S} \cdot \left[\left[\frac{f(2k+1)-1}{2(f+1)} \right] \right].$$
 (1)

The light location becomes heavy location after a cNAMP arrival, and has $\left[\left[\frac{2k-f+1}{2(f+1)}\right]\right]$ cNAMPs. The execution time is

$$T_n = \frac{W_r}{S} \cdot \left[\left[\frac{2k - f + 1}{2(f+1)} \right] \right].$$
⁽²⁾

Condition of a cNAMP movement is

$$\frac{W_r}{S} \cdot \left(\left[\left[\frac{2kf + f - 1}{2(f + 1)} \right] \right] - \left[\left[\frac{2k - f + 1}{2(f + 1)} \right] \right] \right) > T_{comm}.$$
(3)

To satisfy (3) at least $\left[\left[\frac{2kf+f-1}{2(f+1)}\right]\right] - \left[\left[\frac{2k-f+1}{2(f+1)}\right]\right]$ must be positive. However, 2kf < 2k and f - 1 < 1 - f, which means that $\left[\left[\frac{2k+f+1}{2(f+1)}\right]\right] - \left[\left[\frac{2k-f+1}{2(f+1)}\right]\right] \leq 0$. Thus, cNAMPs from the root location never move to a

non-root location in a near-optimal balanced state.

Talk Outline	Background	Greedy Effects and Negotiating AMPs	cNAMP Greedy Effect Analysis	Conclusion & Future Work
			0000 0000	

Probability of the Redundant Movement in Homogeneous Networks (1)

Greedy effect probability in a homogeneous network is a product of the probability of a cNAMP termination from the root location and the probability of a discovery a better opportunity for execution first by a cNAMP from a light location:

$$P = P_{termR} \cdot P_l. \tag{4}$$

To calculate the probability of a cNAMP termination at the root location, assume that cNAMP execution time on locations follows a Poisson distribution. The mean cNAMP execution time on the root, heavy and light locations is given by:

$$T_{loc} = \frac{W \cdot x_{loc}}{S_{loc}} = \frac{W}{R_{loc}}$$

Hence, the rate of cNAMP terminations at the root, heavy and light locations is:

$$\nu_{loc} = \frac{R_{loc}}{W}$$

Assume, that there are N_l light locations and N_h heavy locations in the system. Then probability that a cNAMP terminates at the root location is

$$P_{termR} = \frac{\nu_{root}}{\nu_{root} + \nu_h + \nu_l}$$

or

$$P_{termR} = \frac{R_{root}}{R_{root} + N_h R_h + N_l R_l}.$$
(5)

Natalia Chechina, Peter King, Phil Trinder

Dependable System Group, Heriot-Watt University

Talk Outline	Background	Greedy Effects and Negotiating AMPs	cNAMP Greedy Effect Analysis	Conclusion & Future Work
			0000 0000	

Probability of the Redundant Movement in Homogeneous Networks (2)

cNAMPs from non-root locations have an equal probability of discovering a better opportunity for execution first. The total number of cNAMPs on non-root locations is

$$x_{nonroot} = N_h x_h + N_l x_l. \tag{6}$$

The probability that a cNAMP from a light location discovers better opportunity for execution is the ratio of the total number of cNAMPs on light locations to the total number of cNAMPs on non-root locations:

$$P_I = \frac{N_I x_I}{N_I x_I + N_h x_h}.$$
(7)

Thus, substituting (5) and (7) in (4), we get the following probability of the greedy effect after a cNAMP termination from a near-optimally balanced homogeneous network:

$$P = \frac{R_{root}}{R_{root} + N_h R_h + N_l R_l} \cdot \frac{N_l x_l}{N_l x_l + N_h x_h}.$$
(8)

To investigate the range of values that P can take, we calculate P, changing the total number of locations from 3 to 50, the number of light locations from 1 to N - 2, the load factor, 0.45 < f < 0.55, and the number of cNAMPs. In the calculation we consider only cases when $N_h \cdot N_I \neq 0$, because a system must have both heavy and light locations in order that the greedy effect can occur. The root and light locations must have at least one cNAMP.
